└ Introduction
└ Abstract

This paper presents algorithms for the automatic synthesis of the real time controllers by finding a winning strategy for certain games defined by the timed automata of Alur and Dill.

Consider a dynamical system P , whose presentation describes all its possible behaviours. A subset of the plant's behaviours, satisfying some criterion is defined as good or acceptable.

A controller C is another system which can interact with P in a certain manner by observing the state of P and by issuing control actions that influence the behaviour of P .

└ Introduction

└ The problem

Consider a dynamical system P , whose presentation describes all its possible behaviours. A subset of the plant's behaviours, satisfying some criterion is defined as good or acceptable.

A controller C is another system which can interact with P in a certain manner by observing the state of P and by issuing control actions that influence the behaviour of P .

The synthesis problem is then, to find out whether, for a given P , there exists a realizable controller C such that their interaction will produce only good behaviours.

Definition 1 (Plant)

A plant automaton is a tuple $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ where Q is a finite set of states, Σ_c is a set of controller commands, $\delta : Q \times \Sigma_c \mapsto 2^Q$ is the transition function and $q_0 \in Q$ is an initial state.

Definition 2 (Controllers)

A controller (strategy) for a plant specified by $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ is a function $C : Q^+ \mapsto \Sigma_c$. A simple controller is a controller that can be written as a function $C : Q \mapsto \Sigma_c$.

Definition 1 (Plant)

A plant automaton is a tuple $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ where Q is a finite set of states, Σ_c is a set of controller commands, $\delta : Q \times \Sigma_c \mapsto 2^Q$ is the transition function and $q_0 \in Q$ is an initial state.

Definition 2 (Controllers)

A controller (strategy) for a plant specified by $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ is a function $C : Q^+ \mapsto \Sigma_c$. A simple controller is a controller that can be written as a function $C : Q \mapsto \Sigma_c$.

We are interested in the simpler cases of controllers that base their decisions on a finite memory.

Definition 3 (Trajectories)

Let \mathcal{P} be a plant and let $C : Q^+ \mapsto \Sigma_c$ be a controller. An infinite sequence of states $\alpha : q[0], q[1], \dots$ such that $q[0] = q_0$ is called a trajectory of \mathcal{P} if

$$q[i+1] \in \bigcup_{\sigma \in \Sigma_c} \delta(q[i], \sigma)$$

and a C -trajectory if $q[i+1] \in \delta(q[i], C[\alpha[0..i]])$ for every $i \geq 0$. The corresponding sets of trajectories are denoted by $L(\mathcal{P})$ and $L_C(\mathcal{P})$.

- $\mathcal{R}_1 \mu W \left\{ \pi(W) \cap \nu Y \mu H. W \cup G \cap (\pi(H) \cup (F \cap \pi(Y))) \right\}$

Then the plant is controllable iff $q_0 \in W$

```
W0 := ∅
for i := 1, 1, ... repeat
  Wi+1 := F ∪ π(Wi)
until Wi+1 = Wi
...
finally: Wn := F ∪ π(Wn-1) = F ∪ π(F ∪ π(F))
```

Let see in more details how this works. Consider the case \diamond :

$W_0 := \emptyset$

for $i := 0, 1, \dots$ repeat

$W_{i+1} := F \cup \pi(W_i)$

until $W_{i+1} = W_i$

finally: $W_n := F \cup \pi(W_{n-1}) = F \cup \pi(F \cup \pi(F))$

$W_0 := \emptyset$

$W_1 := F \cup \pi(W_0) = F \cup \pi(W_0) = F$

$W_2 := F \cup \pi(W_1) = F \cup \pi(F)$

...

Discrete Case

In the process of calculating W_{i+1} , whenever we add a state q to W_i , there must be at least one action $\sigma \in \Sigma_c$ such that $\delta(q, \sigma) \subseteq W_i$.

So we define the controller at q as $C(q) = \sigma$.

When the process terminates, the controller is synthesized for all the winning states.

It can be seen that if the process fails, that is $q_0 \notin W$, then for every controller command there is a possibly bad consequence that will put the system outside F , and no controller, even an infinite state one, can prevent this.

Given a timed automaton \mathcal{T} and an acceptance condition Ω , the problem **RT-Synth**(\mathcal{T}, Ω) is: Construct a real-time controller C such that $L_C(\mathcal{T}) \subseteq L(\mathcal{T}, \Omega)$

In order to tackle the real time controller synthesis problem we introduce the following definitions:

Definition 14 ($(t, \sigma) - \text{successor}$)

For $t \in \mathcal{T}$ and $\sigma \in \Sigma$, the configuration (q', x') is defined to be a $(t, \sigma) - \text{successor}$ of the configuration (q, x) if there exists an intermediate configuration (\hat{q}, \hat{x}) such that (\hat{q}, \hat{x}) is a $t - \text{successor}$ of (q, x) and (q', x') is a $\sigma - \text{successor}$ of (\hat{q}, \hat{x}) .

Then we define a function $\delta : (Q \times X) \times (\mathcal{T} \times \Sigma_c^\perp) \mapsto 2^{Q \times X}$ where $\delta((q, x), (t, \sigma))$ stands for all the possible consequences of the controller attempting to issue the command $\sigma \in \Sigma_c^\perp$ after waiting t time units starting at configuration (q, x)

2022-07-12

Automatic Verification

Real Time Case

Control Synthesis for Timed Systems

In order to tackle the real time controller synthesis problem we introduce the following definitions:

Definition 14 ($(t, \sigma) - \text{successor}$)

For $t \in \mathcal{T}$ and $\sigma \in \Sigma$, the configuration (q', x') is defined to be a $(t, \sigma) - \text{successor}$ of the configuration (q, x) if there exists an intermediate configuration (\hat{q}, \hat{x}) such that (\hat{q}, \hat{x}) is a $t - \text{successor}$ of (q, x) and (q', x') is a $\sigma - \text{successor}$ of (\hat{q}, \hat{x}) .

Then we define a function $\delta : (Q \times X) \times (\mathcal{T} \times \Sigma_c^\perp) \mapsto 2^{Q \times X}$ where $\delta((q, x), (t, \sigma))$ stands for all the possible consequences of the controller attempting to issue the command $\sigma \in \Sigma_c^\perp$ after waiting t time units starting at configuration (q, x)

Note that this covers the case of (q', x') being simply a $\sigma - \text{successor}$ of (q, x) by viewing it as a $(0, \sigma) - \text{successor}$ of (q, x) .

Definition 15 (Extended Transition Function)

For every $t \in \mathcal{T}$ and $\sigma \in \Sigma_c$, the set $\delta((q, x), (t, \sigma))$ consists of all the configurations (q', x') such that:

- ▶ (q', x') is a (t, σ) – successor of (q, x)
- ▶ (q', x') is a (t, e) – successor of (q, x) for some $t' \in [0, t]$

2022-07-12

Automatic Verification

└ Real Time Case

└ Control Synthesis for Timed Systems

Definition 15 (Extended Transition Function)

For every $t \in \mathcal{T}$ and $\sigma \in \Sigma_c$, the set $\delta((q, x), (t, \sigma))$ consists of all the configurations (q', x') such that:

- ▶ (q', x') is a (t, σ) – successor of (q, x)
- ▶ (q', x') is a (t, e) – successor of (q, x) for some $t' \in [0, t]$

This definition covers successor configurations that are obtained in one of two possible ways:

some configurations result from the plant waiting patiently at state q for t time units, and then taking a σ -labeled transition according to the controller recommendation, the second possibility is of configurations obtained by taking an environment transition at any time $t' \leq t$

This is in fact the crucial new feature of real-time games - there are no turns and the adversary need not wait for the player's next move.

Definition 16 (Controllable Predecessors)

The controllable predecessors function $\pi : 2^Q \times 2^X \mapsto 2^Q \times 2^X$ is defined for every $K \subseteq Q \times X$ by

$$\pi(K) = \{(q, x) : \exists t \in T \exists \sigma \in \Sigma_c \delta((q, x), (t, \sigma)) \subseteq K\}$$

└ Control Synthesis for Timed Systems

Theorem 2 (Control Synthesis for Timed systems)
Given a timed automaton \mathcal{T} and an acceptance condition
 $\{(F, \square), (F, \diamond), (F, \diamond\square), (F, \square\diamond), (\mathcal{F}, \mathcal{R}_n)\}$
the problem **RT-Synth**(\mathcal{T}, Ω) is solvable

Sketch of Proof

We have just shown that $2^Q \times \mathcal{H}_k^*$ is closed under π .

Any of the iterative processes for the fixed point equations (1) – (5) starts with an element of $2^Q \times \mathcal{H}_k^*$.

For example, the iteration for \diamond starts with $W_0 = Q \times F$.

Each iteration consists of applying Boolean set-theoretic operations and the predecessor operation, which implies that every W_i is also an element of $2^Q \times \mathcal{H}_k^*$ - a finite set.

Thus, by monotonicity, a fixed point is eventually reached.

└ Control Synthesis for Timed Systems

Sketch of Proof

We have just shown that $2^Q \times \mathcal{H}_k^*$ is closed under π .

Any of the iterative processes for the fixed point equations (1) – (5) starts with an element of $2^Q \times \mathcal{H}_k^*$.

For example, the iteration for \diamond starts with $W_0 = Q \times F$.

Each iteration consists of applying Boolean set-theoretic operations and the predecessor operation, which implies that every W_i is also an element of $2^Q \times \mathcal{H}_k^*$ - a finite set.

Thus, by monotonicity, a fixed point is eventually reached.

The strategy is extracted in a similar manner as in the discrete case. When ever a configuration (q, x) is added to W , it is due to one or more pairs of the form $([t_1, t_2], \sigma)$ indicating that within any $t, t_1 < t < t_2$ issuing σ after waiting t will lead to a winning position. Hence by letting $C(q, x) = \perp$ when $t_1 > 0$ and $C(q, x) = \sigma$ when $t_1 = 0$ we obtain a k -polyhedral controller.
