This paper presents algorithms for the automatic synthesis of the real time controllers by finding a winning strategy for certain games defined by the timed automata of Alur and Dill.

Automatic Verification
—Introduction
—Abstract

This paper presents algorithms for the automatic synthesis of the real time controllers by finding a winning strategy for certain games defined by the timed automata of Alur and the controllers.

Introduction

Consider a dynamical system P, whose presentation describes all its possible behaviours. A subset of the plant's behaviours, satisfying some criterion is defined as good or acceptable.

A controller C is another system which can interact with P in a certain manner by observing the state of P and by issuing control actions that influence the behaviour of P.

Automatic Verification

Introduction

The problem

Consider a dynamical system P, whose presentation describe all its possible behaviours. A subset of the plant's behaviours satisfying some criterion is defined as good or acceptable. A controller C is another system which can interact with P in a certain manner by observing the state of P and by issuing control actions that influence the babaviour of P

Introduction

The synthesis problem is then, to find out whether, for a given P, there exists a realizable controller C such that their interaction will produce only good behaviours.

Automatic Verification
—Introduction
—The problem

The synthesis problem is then, to find out whether, for a given P, there exists a realizable controller C such that their interaction will produce only good behaviours.

Definition 1 (Plant)

A plant automaton is a tuple $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ where Q is a finite set of states, Σ_c is a set of controller commands, δ : $Q \times \Sigma_c \longmapsto 2^Q$ is the transition function and $g_0 \in Q$ is an initial state.

Definition 2 (Controllers)

A controller (strategy) for a plant specified by $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ is a function $C: Q^+ \longmapsto \Sigma_c$. A simple controller is a controller that can be written as a function $C: Q \longrightarrow \Sigma_c$.

Automatic Verification Discrete Case Initial Definitions

We are interested in the simpler cases of controllers that base their decisions on a finite memory.

Definition 3 (Trajectories)

Let \mathcal{P} be a plant and let $C: Q^+ \longmapsto \Sigma_c$ be a controller. An infinite sequence of states $\alpha : q[0], q[1], \dots$ such that $q[0] = q_0$ is called a trajectory of P if

$$q[i+1] \in \bigcup_{\sigma \in \Sigma_c} \delta(q[i], \sigma)$$

and a C-trajectory if $q[i+1] \in \delta(q[i], C[\alpha[0..i]])$ for every $i \geq 0$. *The corresponding sets of trajectories are denoted by* L(P)and $L_{\mathcal{C}}(\mathcal{P})$.

4□ > 4□ > 4□ > 4□ > 4□ > 9

Automatic Verification Discrete Case -Initial Definitions

Let P be a plant and let $C: Q^+ \mapsto \Sigma_c$ be a controller. An infinite sequence of states α : o(0), o(1), ... such that o(0) = o(1)

 $q[i+1] \in \bigcup_{\sigma \in \Sigma_{-}} \delta(q[i], \sigma)$

and a C-trajectory if $q[i+1] \in \delta(q[i], C[\alpha[0..i]))$ for every $i \ge i$

For every infinite trajectory $\alpha \in L(\mathcal{P})$:

- \triangleright *Vis*(α) denote the set of all states appearing in α
- Inf(α) denote the set of all states appearing in α infinitely many times

Automatic Verification Discrete Case -Initial Definitions

For every infinite trajectory $\alpha \in L(P)$:

Inf (α) denote the set of all states appearing in α

Vis(α) denote the set of all states appearing in α

Definition 4 (Acceptance Condition)

Let $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ be a plant. An acceptance condition for \mathcal{P} is

$$\Omega \in \{(F, \square), (F, \lozenge), (F, \lozenge \square), (F, \square \lozenge), (\mathcal{F}, \mathcal{R}_n)\}$$

where $\mathcal{F} = \{(F_i, G_i)\}_{i=1}^n$ and F, F_i and G_i are certain subsets of Q referred as the good states. The set of sequences of \mathcal{P} that are accepted according to Ω is defined as follows:

$$\begin{array}{ll} L(\mathcal{P}, F, \square) & \{\alpha \in L(\mathcal{P}) : \textit{Vis}(\alpha) \subseteq F\} \\ L(\mathcal{P}, F, \lozenge) & \{\alpha \in L(\mathcal{P}) : \textit{Vis}(\alpha) \cap F \neq \emptyset\} \\ L(\mathcal{P}, F, \lozenge \square) & \{\alpha \in L(\mathcal{P}) : \textit{Inf}(\alpha) \subseteq F\} \\ L(\mathcal{P}, F, \square \lozenge) & \{\alpha \in L(\mathcal{P}) : \textit{Inf}(\alpha) \cap F \neq \emptyset\} \\ & \{\alpha \in L(\mathcal{P}) : \exists i\alpha \in L(\mathcal{P}, F, \mathcal{R}_n) & L(\mathcal{P}, F_i, \square \lozenge) \cap L(\mathcal{P}, G_i, \lozenge \square)\} \end{array}$$

Automatic Verification

Discrete Case
Initial Definitions

nition 4 (Acceptance Condition)

p is $\Omega \in ((F, \square), (F, \lozenge), (F, \lozenge \square), (F, \square_0), (F, \square_0)$ where $F = ((F, \square))_{i,1}^n$ and F, F_i and G_i are certain of Q referred as the good states. The set of sequeno: that are accepted accordig to D_i is defined as follows: $[(P, F, \square) \quad \{\alpha \in U(P) : Val(\alpha) \subseteq F\}$

 $L(P, F, \Box)$ $\{\alpha \in L(P) : Vs(\alpha) \subseteq L(P, F, \Diamond)\}$ $\{\alpha \in L(P) : Vs(\alpha) \cap L(P, F, \Diamond \Box)\}$ $\{\alpha \in L(P) : Inf(\alpha) \subseteq L(P, F, \Box \Diamond)\}$ $\{\alpha \in L(P) : Inf(\alpha) \cap \{\alpha \in L(P) : \exists i\alpha\}\}$

- 1. α always remains in F
- 2. α eventually visits F
- 3. α eventually remains in F
- 4. α visits F infinitely often
- 5. α visits F_i infinitely often and eventually stays in G_i

Definition 5 (Controller Synthesis Problem)

For a plant \mathcal{P} and an acceptance condition Ω , the problem $\textbf{Synth}(\mathcal{P}, \Omega)$ is: Find a controller C such that $L_C(\mathcal{P}) \subseteq L(\mathcal{P}, \Omega)$ ot otherwise show that such a controller does not exists.

Automatic Verification

Discrete Case
Initial Definitions

Definition 5 (Controller Synthesis Problem)

For a plant P and an acceptance condition Ω, the pr

Synth(P, Q) is Find a controller C such that L (P) C.

Definition 6 (Controllable Predecessors)

Let $\mathcal{P} = (Q, \Sigma_c, \delta, q)$ be a plant and a set of states $P \subseteq Q$. The controllable predecessors of P is the set of states from which the controller can "force" the plant into P in one step:

$$\{q:\exists\sigma\in\Sigma_c\cdot\delta(q,\sigma)\subseteq P\}$$

We define a function $\pi: 2^Q \longrightarrow 2^Q$, mapping a set of states $P \subseteq Q$ into the set of its Controllable predecessors:

$$\pi(P) = \{q : \exists \sigma \in \Sigma_c \cdot \delta(q, \sigma) \subseteq P\}$$

4□ > 4□ > 4□ > 4□ > 4□ > 9

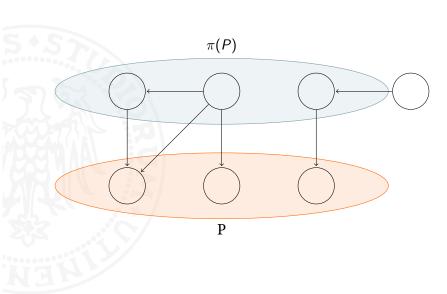

Automatic Verification Discrete Case Controllable Predecessors

 $\{a : \exists \sigma \in \Sigma_{\sigma}, \delta(a, \sigma) \subseteq P\}$

We define a function $\pi: 2^Q \longrightarrow 2^Q$, mapping a set of stat P ⊂ O into the set of its Controllable predecessors

 $\pi(P) = \{q : \exists \sigma \in \Sigma_c . \delta(q, \sigma) \subseteq P\}$

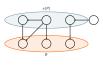

Automatic Verification

Discrete Case

Controllable Predecessors

Theorem 1

For every $\Omega \in \{(F, \square), (F, \lozenge), (F, \lozenge \square), (F, \square \lozenge), (\mathcal{F}, \mathcal{R}_n)\}$, the problem **Synth**(\mathcal{P}, Ω) is solvable. Moreover, if (\mathcal{P}, Ω) is controllable then it is controllable by a simple controller.

For a plant $\mathcal{P} = (Q, \Sigma_c, \delta, q_0)$ and an acceptance condition Ω , we denote $W \subseteq Q$ as the set of winning states, namely, the set of states from which a controller can enforce good behaviors according to Ω .

Automatic Verification Discrete Case -Theorem

We can characterize this states by the following fixed-point expressions:

$$\square \ \nu W(F \cap \pi(W))$$

$$\Diamond \ \nu W(F \cup \pi(W))$$

$$\Diamond \Box \ \mu W \nu H \Big(\pi(H) \cap (F \cup \pi(W)) \Big)$$

$$\Box \Diamond \ \nu W \mu H \Big(\pi(H) \cup (F \cap \pi(W)) \Big)$$

$$\mathcal{R}_1 \ \mu W \bigg\{ \pi(W) \cap \nu Y \mu H.W \cup G \cap \big(\pi(H) \cup (F \cap \pi(Y))\big) \bigg\}$$

Then the plant is controllable iff $q_0 \in W$

```

\mu least
```

Let see in more details how this works. Consider the case ◊:

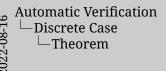

$$egin{aligned} &W_0 := \emptyset \ & W_0 := \emptyset \ & \text{for } i := 0, 1, \dots \ & ext{repeat} \end{aligned} \qquad egin{aligned} &W_1 := F \cup \pi(W_0) = F \cup \pi(\emptyset) = F \ & W_{i+1} := F \cup \pi(W_i) \end{aligned} \qquad egin{aligned} &W_2 := F \cup \pi(W_1) = F \cup \pi(F) \ & \text{until } W_{i+1} = W_i \end{aligned} \qquad \dots$$

finally: $W_n := F \cup \pi(W_{n-1}) = F \cup \pi(F \cup \pi(...(F \cup \pi(F))))$

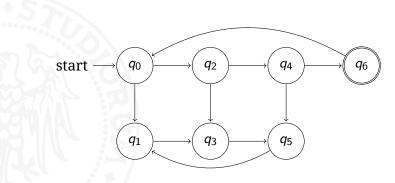

Automatic Verification Discrete Case -Theorem

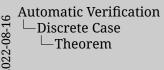

finally: $W_n := F \cup \pi(W_{n-1}) = F \cup \pi(F \cup \pi(...(F \cup \pi(F))))$

◆□▶◆□▶◆□▶◆□▶ ■ 夕久○

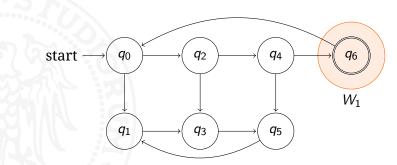

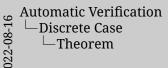

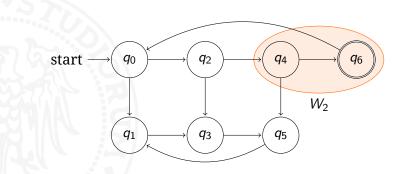

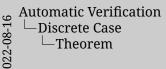

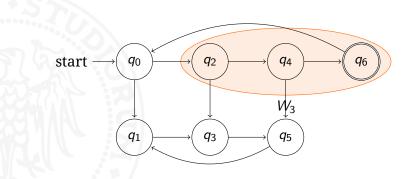

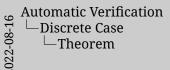

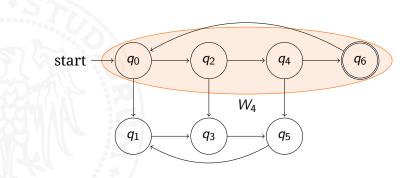

In the process of calculating W_{i+1} , whenever we add a state q to W_i , there must be at least one action $\sigma \in \Sigma_c$ such that $\delta(q, \sigma) \subseteq W_i$.

So we define the controller at q as $C(q) = \sigma$.

When the process terminates, the controller is synthesized for all the winning states.

It can be seen that if the process fails, that is $q_0 \notin W$, then for every controller command there is a possibly bad consequence that will put the system outside F, and no controller, even an infinite state one, can prevent this.

Conclusions

In the process of calculating W_{i+1} , whenever we add a state q to W_i , there must be at least one action $\sigma \in \Sigma_c$ such that $\delta(q, \sigma) \subseteq W_i$. So we define the controller at σ as $C(\sigma) = \sigma$.

When the process terminates, the controller is synthesize

for all the winning states. It can be seen that if the process fails, that is $q_0 \notin W$, then for every controller command there is a possibly bad consequence that will put the system outside F, and no controller, even an infinite state one, can prevent this.

Timed automata are automata equipped with clocks whose values grow continuously.

Let T denote \mathbb{R}^+ and let $X = T^d$ (the clock space).

The elements of X are $x = (x_1, ..., x_d)$ and the d-dimensional unit vector is $\mathbf{1} = (1, ..., 1)$

Definition 7 (Reset functions)

Let F(X) denote the class of functions $f: X \mapsto X$ that can be written in the form $f(x_1, ..., x_d) = (f_1, ..., f_d)$ where each f_i is either x_i or 0.

4 D > 4 A > 4 B > 4 B > 9 Q P

Timed automata are automata equipped with clocks whose values grow continuously. Let τ denote π ' and let $x - \tau'$ (the clock space). The elements of X are $x = (a, \dots, a)$ and the d-dimensional unit vector is $1 - (1, \dots, 1)$. Definition T (Recent functions)

Let T(X) denote the class of functions $t: X \to X$ that can be written in the form $T(\alpha, \dots, a) = (a, \dots, a)$ where each t is

The clocks interact with the transitions by participating in preconditions (guards) for certain transitions and they are possibly reset when some transitions are taken

Definition 8 (k polyhedral sets)

Let k be a positive integer constant. We associate with k three subsets of 2^{X} :

- \triangleright \mathcal{H}_k : the set of half-spaces consisting of all sets having one of the following forms
 - λ
 - **>** Ø

 - $\{x \in X : x_i x_i \# c\}$

for some $\# \in \{<, \leq, >, \geq\}$ and $c \in \{0, ..., k\}$

- \blacktriangleright \mathcal{H}_k^{\cap} : the set of convex sets consisting of intersections of elements of \mathcal{H}_k
- \mathcal{H}_k^* : the set of k-polyhedral sets containing all sets obtained from \mathcal{H}_k via union intersection and complementation

Automatic Verification

Real Time Case
Initial Definitions

Let k be a positive integer constant. We associate with three subsets of 2^x: H_k: the set of half-spaces consisting of all sets having

- ► H_k: the set of half-spaces consisting of all sets i one of the following forms
 ➤ X
- ► X ► ∅ ► {x ∈ X : x, ∅ c}
- $\{x \in X : x_i x_j \# c\}$ for some $\# \in \{<, \le, >, \ge\}$ and $c \in \{0, ..., k\}$ $N^0: \text{the ratio fragment extraordistips of intervals.}$
- In some w∈ {<, ≤, >, <} and ∈ ∈ {0,..., κ}
 H_k^{*}: the set of convex sets consisting of intersections elements of H_k
 H_k: the set of k-polyhedral sets containing all sets

Definition 9 (Timed Automata)

A timed automaton is a tuple $\mathcal{T} = (Q, X, \Sigma, I, R, q_0)$ consisting of:

- Q a finite set of discrete states
- ightharpoonup X a clock domain $X = (\mathbb{R}^+)^d$ for some d > 0
- $\triangleright \Sigma = \Sigma_c \cup \{e\}$ an input alphabet (including a single environment action e)
- $ightharpoonup I: Q \mapsto \mathcal{H}^{\cap}_{k}$ as the state invariant function
- $ightharpoonup R \subseteq Q \times \Sigma \times \mathcal{H}_{k}^{\cap} \times F(X) \times Q$ is a set of transition relations each of the form $\langle q, \sigma, g, f, q' \rangle$ where:
 - ightharpoonup q, q' in Q
 - $\sigma \in \Sigma$
 - $p \in \mathcal{H}^{\cap}_{k}$
 - $ightharpoonup f \in F(X)$

Definition 9 (Timed Automata) A timed automaton is a tuple $T = (O \times \Sigma \mid R \mid e_0)$ consisting

- Q a finite set of discrete states
- X a clock domain X = (R+)^d for some d > 0
- - g ∈ H_k
 f ∈ F(X)

A *configuration* of \mathcal{T} is a pair $(q, x) \in Q \times X$ denoting a discrete state and the values of the clocks.

Without loss of generality, we assume that:

$$\forall q \in Q, \forall x \in X \exists t \in T : x + 1t \notin I_q$$

Automatic Verification
Real Time Case
Initial Definitions

A configuration of T is a pair $(q, x) \in Q \times X$ denoting a crete state and the values of the clocks. Without loss of generality, we assume that: $\forall q \in Q, \forall x \in X \exists t \in T: x + 1 t \neq I_x$

That is, the automaton cannot stay in any of its discrete states forever.

$$x+1t=(x_1,\ldots,x_n)+(1,\ldots,1)t=(x_1+t,\ldots,x_n+t)$$
 The time has the same pace in all clocks

Definition 10 (Steps and Trajectories)

A step of \mathcal{T} is a pair of configurations ((q, x), (q', x')) such that either:

- ▶ q = q' and for some $t \in T, x' = x + 1t, x \in I_q$ and $x' \in I_q$. In this case we say that (q', x') is a t-successor of (q, x) and that ((q, x), (q', x')) is a t-step.
- ► There is some $r = \langle q, \sigma, g, f, q' \rangle \in R$ such that $x \in g$ and x' = f(x). In this case we say that (q', x') is a σ -successor of (q, x) and that ((q, x), (q', x')) is a σ -step

A trajectory of \mathcal{T} is a sequence $\beta = (q[0], x[0]), (q[1], x[1]), \ldots$ of configurations such that for every i, ((q[i], x[i]), (q[i+1], x[i+1])) is a step.

4 D > 4 D > 4 E > 4 E > 9 Q O

ition 10 (Steps and Trajectories)

- A step of T is a pair of configurations ((q, x), (q', x' either:
- q = q' and for some t ∈ 1, x' = x + 11, x ∈ l_q a In this case we say that (q', x') is a t-successor and that ((q, x), (q', x')) is a t-step.
- There is some r = (q, σ, g, f, q') ∈ R such that x ∈ g and x' = f(x). In this case we say that (q', x') is a σ-successo of (q, x) and that ((q, x), (q', x')) is a σ-step

A trajectory of T is a sequence $\beta = (q[0], x[0]), (q[1], x[1]), ...$ of configurations such that for every i, ((q[i], x[i]), (q[i+1], x[i+1])) is a step.

Definition 11 (Real time Controller)

A simple real time controller is a function $C: Q \times X \mapsto \Sigma_c \cup \bot$

According to this function the controller chooses at any configuration (q,x) whether to issue some enabled transition σ or to do nothing and let time go by. We denote by $\Sigma_c^{\perp} = \Sigma_c \cup \bot$ the range of controller commands. We also require that the controller is k-polyhedral, i.e., for every $\sigma \in \Sigma_c^{\perp}$, $C^{-1}(\sigma)$ is a k-polyhedral set.

4 D > 4 P > 4 B > 4 B > B = 900

Given a simple controller C, a pair ((q,×), (q',×')) o urations is a C-step if it is either: an e – step

a σ – step such that C(q, x) = σ ∈ Σ_c
 a t – step for some t ∈ T such that for every t'
 t' ∈ [0, t), C(q, x + 1t') = ⊥

A C-trajectory is a trajectory consisting of C-steps. We denote the set of C-trajectories of T by $L_{*}(T)$

Definition 13 (Real time Controller Synthesis)

Given a timed automaton \mathcal{T} an a acceptance condition Ω , the problem RT-Synth (\mathcal{T}, Ω) is: Construct a real-time controller C such that $L_C(\mathcal{T}) \subseteq L(\mathcal{T}, \Omega)$

Automatic Verification
Real Time Case
Real Time Controllers

Definition 13 (Real time Controller Synthesis) Given a timed automaton T an a acceptance condition problem RT-Synth(T, Ω) is: Construct a real-time con C such that $L_{C}(T) \subseteq L(T, \Omega)$

In order to tackle the real time controller synthesis problem we introduce the following definitions:

Definition 14 ((t, σ) – successor)

For $t \in T$ and $\sigma \in \Sigma$, the configuration (q',x') is defined to be a (t,σ) – successor of the configuration (q,x) if there exists an intermediate configuration (\hat{q},\hat{x}) such that (\hat{q},\hat{x}) is a t – successor of (q,x) and (q',x') is a σ – successor of (\hat{q},\hat{x}) .

Then we define a function $\delta: (Q \times X) \times (T \times \Sigma_c^{\perp}) \mapsto 2^{Q \times X}$ where $\delta((q, x), (t, \sigma))$ stands for all the possible consequences of the controller attempting to issue the command $\sigma \in \Sigma_c^{\perp}$ after waiting t time units starting at configuration (q, x)

Automatic Verification

Real Time Case
Control Synthesis for Timed Systems

introduce the following definitions: $f(t, \sigma) = successor$

Por $t \in T$ and $\sigma \in \Sigma$, the configuration $(q', t_0) = successor$, of the configuration

Then we define a function $\delta: (Q \times X) \times (T \times \Sigma_c^{\perp}) \mapsto 2^{Q \times X}$ where $\delta((q, x), (t, \sigma))$ stands for all the possible consequence of the controller attempting to issue the command $\sigma \in \Sigma_c^{\perp}$

Note that this covers the case of (q', x') being simply a σ – *successor* of (q, x) by viewing it as a $(0, \sigma)$ – *successor* of (q, x).

Definition 15 (Extended Transition Function)

For every $t \in T$ and $\sigma in \Sigma_c$, the set $\delta((q, x), (t, \sigma))$ consists of all the configurations (q', x') such that:

- \triangleright (q', x') is a (t, σ) successor of (q, x)
- (q',x') is a (t,e) successor of (q,x) for some $t' \in [0,t]$

Automatic Verification
Real Time Case

Control Synthesis for Timed Systems

This definition covers successor configurations that are obtained in one of two possible ways:

some configurations result from the plant waiting patiently at state q for t time units, and then taking a σ -labeled transition according to the controller recommendation,

the second possibility is of configurations obtained by taking an environment transition at any time $t' \le t$

This is in fact the crucial new feature of real-time games - there are no turns and the adversary need not wait for the player's next move.

Definition 16 (Controllable Predecessors)

The controllable predecessors function $\pi: 2^Q \times 2^X \mapsto 2^Q \times 2^X$ is defined for every $K \subseteq Q \times X$ by

$$\pi(K) = \{(q, x) : \exists t \in T \exists \sigma \in \Sigma_c \ \delta((q, x), (t, \sigma)) \subseteq K\}$$

Automatic Verification
Real Time Case
Control Synthesis for Timed Systems

Definition 16 (Controllable Predecessors)

The controllable predecessors function $\pi : 2^Q \times 2^X \mapsto 2^Q \times 1^X$ is defined for every $K \subseteq Q \times X$ by $\pi(K) = \{(q, x) : \exists t \in T \exists \sigma \in \Sigma_c \ \delta((q, x), (t, \sigma)) \subseteq K\}$

As in the discrete case, we define a predecessor function that indicates the configurations from which the controller can force the automaton into a given set of configurations

Assume that $Q = \{q_0, \dots, q_m\}$. Clearly, any set of configurations ca be written as $K = \{q_0\} \times P_0 \cup \ldots \cup \{q_m\} \times P_m$ where P_0, \ldots, P_m are subsets of X.

Thus the set K can be uniquely represented by a set tuple $\mathcal{H} = \langle P_0, \dots, P_m \rangle$ and we can view π as a transformation on set tuples.

Automatic Verification

Real Time Case
Control Synthesis for Timed Systems

Assume that $Q = \{q_0, \dots, q_m\}$. Clearly, any set of configures tons ca be written as $K = \{q_0\} \times P_0 \cup \dots \cup \{q_m\} \times P_m$ where $q_0 \in P$ are subset of X.

Thus the set K can be uniquely represented by a set tuple $\mathcal{H} = (P_0, \dots, P_m)$ and we can view π as a transformation on set tuples

Theorem 2 (Closure of \mathcal{H}_k^* under π)

if
$$\mathcal{H} = \langle P_0, \dots, P_m \rangle$$
 is k-polyhedral so is $\pi(\mathcal{H}) = \langle P_0, \dots, P_m \rangle$

one $r = (q, \sigma, g, f, q') \in R$. Let $(P'_0, \dots, P'_m) = \pi((P_0, \dots, P_m))$. Then, for each $i = 0, \dots, m$ then set P'_i can be expressed as:

$$P_i^r = \bigcup_{(\mathbf{z}_i, \mathbf{z}_i, \mathbf{z}_i, \mathbf{z}_i) \in \mathbb{R}} \{\mathbf{x} : \exists \mathbf{r} \in \mathcal{T} \mid \begin{array}{l} \mathbf{x} \in I_{\mathbf{z}_i} \land \\ \mathbf{x} + \mathbf{1}\mathbf{r} \in I_{\mathbf{z}_i} \land \\ \mathbf{x} + \mathbf{1}\mathbf{r} \in I_{\mathbf{z}_i} \land \\ \mathbf{x} + \mathbf{1}\mathbf{r} \in \mathcal{F}_i \land \\ f(\mathbf{x} + \mathbf{1}\mathbf{r}) \in P_i \land \\ f(\mathbf{x} + \mathbf{1}\mathbf{r}) \in P_i \land \\ f(\mathbf{x} + \mathbf{1}\mathbf{r}) \in \mathcal{F}_i \land \\ f(\mathbf{x} + \mathbf{1}\mathbf{r}) \in \mathcal{F}_i$$

It can be verified that every P'_i can be written as a boolean combinations of sets of the form:

$$I_{q_i} \cap \{x: \exists t \in T \ x+1t \in I_{q_i} \cap g \cap f^{-1}(P_j) \ \forall t' \leq t \ x+1t' \in \overline{g'} \cup f'^{-1}(P_k)\}$$

for some guards g, g' and reset functions f, f', where we use $f^{-1}(P) = \{x : f(x) \in P\}$.

Since timed reachability is distributive over union, i.e.,

$$\{x: \exists t \ x+1t \in S_1 \cup \S_2\} = \{x: \exists t \ x+1t \in S_1\} \cup \{x: \exists t \ x+1t \in \S_2\}$$

it is sufficient to prove the claim assuming *k*-convex polyhedral sets.

4 D > 4 D > 4 D > 4 D > 4 D > 4 D >

Real Time Case
Control Synthesis for Timed Systems

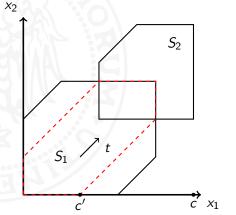

It can be verified that every P_i can be written as a boolean combinations of sets of the form: $t_e \cap \{s: \exists e \ T \ s+1i: e \ t_e \cap g \cap f^{-1}(P_i) \ \forall \le t \ s+1i: e \ \overline{g} \cup f^{-1}(P_i)\}$ for some guards g, g' and reset functions f, f', where we use

 $f^{-1}(P) = \begin{cases} x : f(x) \in P \end{cases}$. Since timed reachability is distributive over union, i.e., $\{x : \exists t \ x+1r \in S_t \cup \S_2\} = \{x : \exists t \ x+1t \in S_1\} \cup \{x : \exists t \ x+1t \in \S_2\}$ it is sufficient to prove the claim assuming &-convex polyhe-

The domani of $f^{-1}(P) = \{x : f(x) \in P\}$ is \mathbb{R}^{+d}

$$\pi_{t',t}(S_1,S_2) = \{x : \exists t \ x + 1t \in S_2 \land \forall t' \leq t \ x + 1t' \in S_1\}$$

is also convex.

Theorem 3 (Control Synthesis for Timed sy

 $\{(F, \Box), (F, \Diamond), (F, \Diamond \Box), (F, \Box \Diamond), (i)\}$ the problem RT-Synth (T, Ω) is solvable

Sketch of Proof

We have just shown that $2^Q \times \mathcal{H}_k^*$ is closed under π .

Any of the iterative processes for the fixed point equations (1) - (5) starts with an element of $2^Q \times \mathcal{H}_k^*$.

For example, the iteration for \Diamond starts with $W_0 = Q \times F$.

Each iteration consists of applying Boolean set-theoretic operations and the predecessor operation, which implies that every W_i is also an element of $2^Q \times \mathcal{H}_k^*$ - a finite set.

Thus, by monotonicity, a fixed point is eventually reached.

Automatic Verification Real Time Case Control Synthesis for Timed Systems

Sketch of Proof

We have just shown that $2^{\circ} \times R_1^{\circ}$ is closed under π . Any of the iterative processes for the fixed point equations (i)— (s) starts with an element of $2^{\circ} \times R_1^{\circ}$. For example, the iteration for α starts with $W_0 = Q \circ F$. Each iteration consists of applying Boolean set theoretic operations and the predecessor operation, which implies that every W_1 is also an element of $2^{\circ} \times R_1^{\circ} \times R_1^{\circ}$ in fixen see. Thus, be monomorphism G and the second of the second of G in the second of G is the second of G in the second of G is a second of G in the second of G is a second of G in the second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the second of G is a second of G in the second of G in the s

The strategy is extracted in a similar manner as in the discrete case. When ever a configuration (q,x) is added to W, it is due to one or more pairs of the form $([t_1,t_2],\sigma)$ indicating that within any $t,t_1 < t < t_2$ issuing σ after waiting t will lead to a winning position. Hence by letting $C(q,x) = \bot$ when $t_1 > 0$ and $C(q,x) = \sigma$ when $t_1 = 0$ we obtain a k-polyhedral controller.
